Information and communication technologies to support patients with long term conditions

How nurses can develop and implement initiatives using information and communication technologies to support patients with long term conditions

There are 15.4 million people with long term conditions in England (Department of Health, 2009) and their care can be enhanced by using ICT. Davies (2006) showed that technology has made it easy for patients to access high quality, evidence-based information, making them more informed and able to manage their conditions more effectively.

SERVICE AGENDAS
Lord Darzi’s NHS Next Stage Review highlighted the need for quality care that is patient centred and more flexible (DH, 2008). This will help patients with busy lifestyles to manage their care.

Using technologies, nurses have the potential to reshape how they work, to provide care tailored to the needs of the increasing numbers of patients with long term conditions. Using a range of ICT will lead to both better quality and increased personalisation of patient care.

The NMC (2009) consultation on core competencies for nurses places skills in managing ICT and information literacy as a core requirement. The DH Modernising Nursing Careers strategy argued that nursing care should be based on evidence and critical thinking and aided by new technology (Centre for the Development of Healthcare Policy and Practice, 2008).

Fisk (2008) suggested that the use of ICT could change power relationships between practitioners and patients. As patients use technologies, they have access to more information. They expect and demand faster responses. Fisk (2008) showed this change in practice is challenging for nurses since they find it more difficult to establish a rapport with patients familiar with using technologies.

However, if the use of alternative forms of communication can be harnessed, this may enable nurses to develop a more patient-centred approach to care. For example, if the use of technologies enables people with long term conditions to take a more active role in setting goals and understanding the choices available to them, this can surely only increase opportunities to optimise health (Barlow, 2006).
Shanit et al (1996) showed how a remote access cardiac support system could help people with long term heart conditions. They used handheld electrocardiogram monitoring devices equipped with a memory card to transfer data. This data informed the GP’s discussion about the patient’s condition with a specialist registrar.

Since then, there has been a rapid expansion in more sophisticated computer-assisted technologies. This has brought about further opportunities for changes in nurses’ communication strategies.

In a study of computer-assisted assessment, Horton (2008) showed that patients with chronic obstructive pulmonary disease were able to use an electrical sphygmomanometer and thermometer to send data to a base computer. A community nurse was then able to offer telephone advice. Patients who were maintaining their condition felt this was beneficial since it offered them effective contact with a clinical nurse specialist while minimising interaction time.

The UK national chlamydia screening programme is an example of harnessing technologies for advice, diagnostic screening and treatment (www.chlamydiascreening.nhs.uk). It uses telephone, SMS, online order and email to offer a comprehensive communication strategy.

The Southampton Hand Assessment Procedure (SHAP) illustrates the potential for innovation in ICT, in developing simulated diagnostic assessments (Ford, 2009; www.shap.ecs.soton.ac.uk).

Fig 1 shows the range of technologies while Table 1 (p16) outlines the advantages and disadvantages of ICT in healthcare.

ICT FIT FOR PURPOSE
A wide range of ICTs are available to nurses. Effective and efficient use of these requires a range of skills.

ICT must be fit for purpose (RCN, 2008), so when adapting technologies, nurses need to consider the needs of the target group.

For example, in the national chlamydia screening programme, the target group is young people aged 15-24. Since many in this group are likely to be confident in using ICTs the programme has adopted a range of technologies to target them.

However, it is important not to make assumptions, since some young people may not have access to ICT while older people may have sophisticated access and skills.

QUESTIONS TO CONSIDER
When developing ways of working with patients using ICT, nurses need to consider the evidence and the resources they will need. Consideration should include:

- Why is ICT considered an appropriate way to support a particular patient group?
- Have you made a baseline profile of the numbers and types of patients it may suit?
- Does your employer have a strategy to develop patient-focused ICT initiatives?
- Do you have support from management?
- What technologies are available and are they compatible with other health and social care provision?
- Do you have sufficient knowledge of the types of technologies available?
- Will the client group have access to and skills in using the technologies?
- Are training opportunities available to improve your skills in using ICT?
- Are staff available who can help design and monitor the ICT development?
- What is your timescale for developing a patient-focused support programme?
- How will you test the effectiveness of the programme before rolling it out to patients?
- How will you evaluate the programme?

CONCLUSION
Nurses need to consider engaging with ICT to meet the challenge of contributing to the design of high quality healthcare.

They need to develop flexible and purposeful methods of care management to meet the needs of the increasing numbers of people with long term conditions. This will require them to develop skills in designing and managing communication strategies that optimise use of resources. One way this could be achieved is by engaging with ICT programmes to discover new ways of connecting with patients.
